Symptoms include unsteady gait, visual sheaths leads to loss of nerve function. Destruction of myelin oligodendrocytes, possibly triggered response. In MS they attack bacteria as part of the body’s immune Microglia normally ingest cell debris and axons in the central nervous system. Oligodendrocytes form sclerosis (MS). Oligodendrocytes form branched. This is of microglial cells (round) ingesting oligodendrocytes (branched). This is the process thought to occur in multiple sclerosis (MS). Oligodendrocytes form insulating myelin sheaths around nerve axons in the central nervous system. Microglia normally digest cell debris and bacteria as part of the body’s immune response. In MS they attack oligodendrocytes, possibly triggered by a virus in people with hereditary susceptibility. Destruction of myelin sheaths leads to loss of nerve function. Symptoms include unsteady gait, visual and speech defects, and paralysis. Magnification: x670 when 10cm wide.
